Summary

Childhood obesity is increasing dramatically and is associated with several cardiometabolic comorbidities. Physical activity has been accepted as an important mean for its prevention. However, only few studies have investigated the impact of a team sports intervention on cardiometabolic risk factors (CMRF), inflammatory markers and cardiorespiratory fitness in obese children. The purpose of the present study was to examine the effects of a 6-month intervention of soccer practice on the body composition, CMRF and inflammatory markers, cardiorespiratory fitness and psychological status of obese children. Eighty eight boys (8-12 yrs; body mass index [BMI] > than CDC 95th percentile) were randomly assigned to 6-months' exercise or non-exercised program: 29 were assigned to a soccer program (SG), 29 were assigned to a traditional physical activity program (TG) and 30 were assigned as a control group (CG). The soccer and traditional physical activity programs involved sessions 60-90 min, 3 times/week; average intensity >70-80%HRmax. Both groups participated in two sessions of 45-90-minutes physical education per week at school. Height, body mass, waist circumference, blood pressure, fasting blood glucose, high-density lipoprotein-cholesterol, triglycerides, insulin, adiponectin, leptin, resistin, C-reactive protein, tumor necrosis factor alpha, oxidized low density lipoprotein cholesterol and maximal oxygen consumption ($\text{VO}_{2\text{max}}$) were evaluated according to standardized procedures. Body composition was assessed by DXA. Indicators of perceived psychological status included body image, self-esteem, attraction to participation in physical activity, perceived physical competence and quality of life measured with standardized questionnaires. Physical activity levels was monitored with accelerometers for 7 days. From baseline through 6 months, the two physical activity groups (SG and TG) showed improvements in body composition, lipid profile, insulin sensitivity, CMRF and inflammatory status, cardiorespiratory fitness and psychological status compared to the CG. The improvement in some variables was more apparent in SG than TG. These findings provide evidence that soccer as a highly popular socially and culturally meaningful sport accessible to all social strata is a highly effective medium for the prevention/reduction of childhood obesity and for the enhancement of body composition, cardiometabolic health, cardiorespiratory fitness and associated psychological status of obese youth.

I. INTRODUCTION

Childhood overweight and obesity have reached epidemic proportions [1]. Approximately 25% of children in developed countries are currently overweight or obese. Prevalence has doubled in Portugal in the last two decades [2]. The increasing prevalence of childhood obesity is associated with an increase in cardiovascular and metabolic risk and comorbidities [3]. Evidence also has suggested that cardiovascular and metabolic risk factors (CMRF) in youth may persist throughout life even in the presence of improved nutritional status and may compromise quality of life as well as life expectancy [4].

For all these reasons, childhood obesity and CMRF represent serious health conditions that need treatment in order to prevent the development of additional health consequences. Physical activity has been accepted as an important means for its prevention [5, 6]. Evidence concerning the effectiveness of physical activity interventions to tackle childhood obesity and CMRF has been reviewed [6-8]. These studies have shown positive effects of physical activity on CMRF, body composition and associated psychological consequences in overweight and obese children. Though interesting, these studies emphasize a need for further research for three reasons. First, results are not entirely congruent across studies. Second, sample sizes varied considerably among studies. And third, physical activity programs varied in intensity, duration, type and setting. Intervention physical activity programs for overweight and obese children have generally incorporated a variety of aerobic and resistance activities accommodating individual differences in physical activity interests (running and walking), and rarely link children's interests to team-games and sport activities (see, for example, [7, 9-11]).

Current recommendations from select panels and international health organizations [12] suggest that children should accumulate at least 60 minutes or more of aerobic moderate- to vigorous-intensity physical activity per day, and to perform muscle and bone-strengthening activities at least 3 days per week. Participation in activities that are appropriate for age and enjoyable, and offer variety is recommended [13]. In Portugal, more than 60% of the children do not reach the recommendations [14]. Factors responsible for this low compliance are not well understood. A plausible explanation is probably linked to limited possibilities of undertaking recommended physical activity (i.e., type, duration, frequency and intensity) in many school and community settings. Another

possible explanation is that children perceive prescribed physical activity as not enjoyable because it is superimposed by others and not self-chosen. The data for Portugal are generally consistent with the increasing prevalence of physical inactivity among children worldwide; it is estimated that about two-thirds of the child population are insufficiently physically active [15].

Soccer is a popular, affordable, and widely practiced team-sports worldwide and has been recently suggested as a very effective “tool” in reducing CMRF in adults [16]. Traditionally played as 11 vs. 11, but also as small-sided games (e.g. 3v3, 5v5, 7v7), football is associated with relatively high energy expenditure and a high aerobic component, with mean heart rates (HR) of 75-85% of maximum HR [17, 18]. Recreational soccer also involves high impact activities which stimulate the muscular-skeletal system. The efficacy of a recreational soccer program on health and fitness of overweight children has been recently investigated [19, 20]. While no detailed CMRF were assessed, this novel data suggested that soccer has a high positive effect in weight control. Given this novelty, we believe that soccer being a highly popular sport, socially and culturally meaningful and accessible to all social strata has an increased potential to operate as a highly effective “medicine” for the prevention/reduction of childhood obesity and CMRF.

Thus, based on a 6-month randomized trial design, this study aimed to provide adequate answers to the following hypotheses:

- (1) Systematic practice of recreational soccer has a significant effect in reducing CMRF and percentage of body fat, and in improving muscle and bone mass, cardiorespiratory fitness and associated psychological consequences;
- (2) Systematic practice of recreational soccer has a greater effect than other traditional physical activity intervention program in increasing energy expenditure, reducing CMRF, and improving body composition, cardiorespiratory fitness and associated psychological consequences;
- (3) With recreational soccer as the template for regular physical activity or reducing the expression of CMRF, new subsets of markers with greater sensitivity and predictive and clinical utility will be developed.

II. STATE OF THE ART

The increasing prevalence of childhood obesity [1] is associated with an increase in CMRF and comorbidities [3]. Evidence also suggests that CMRF in youth may persist (track) throughout life even in the presence of improved nutritional status [21] compromising the quality of life and its expectancy [4]. Abdominal obesity, high blood pressure, elevated triglycerides and glucose, and reduced levels of high-density lipoprotein are commonly clustered as the metabolic syndrome [22]. Although variably defined, prevalence of metabolic syndrome has increased recently and has reached 15-17% among Portuguese obese children [2, 23]. If risk factor aggregation, rather than traditional criteria for metabolic syndrome, is used, more than one-half of obese children have two or more risk factors [24]. This approach suggests that classical markers may not be sufficiently sensitive at pediatric ages and highlight a need to consider other markers of CMRF. Recent research suggested the existence of other biological markers associated with pro-inflammatory and pro-oxidant states which are expressed at earlier ages with greater sensitivity [24, 25]. These novel markers are adiponectin and its isoforms, leptin, resistin, high sensitivity C-reactive protein (CRP), tumor necrosis factor alpha (TNF- α) and lipoprotein particularly its oxidized high-density (LDL-ox). Cytokines are precocious markers of CMRF associated with obesity. Some have a pro-inflammatory action (TNF- α , IL-6), are significantly higher in the plasma of obese patients and triggers an increased synthesis of hsCRP [26]. This inflammation may promote CMRF comorbidities of obesity, namely dislipidemia, insulin resistance and endothelial dysfunction. This is the reason why obesity may be regarded as a state of low grade inflammation and atherosclerosis. In contrast, adiponectin decreased plasma concentration in obese is associated with an anti-inflammatory status and an antiatherogenic and antidiabetic profile, meaning that adiponectin acts as a precocious and independent biomarker of metabolic syndrome [27].

Childhood obesity and CMRF represent serious health conditions that must be treated in order to prevent the development of additional health consequences. Physical activity has been accepted as an important means for its prevention [23]. The evidence concerning the effectiveness of PA interventions to tackle childhood obesity and CMRF has been reviewed [6-8]. These studies have shown positive effects of physical activity on body composition, CMRF, cardiorespiratory fitness and psychological status in obese children. However, there is a consistently call for future research centered on

intervention novelty and innovative biological markers. The inconsistency of available data involved a wide range in sample sizes, physical activity programs with different intensities, durations, frequencies and types of activities. Intervention physical activity programs for obese children have generally incorporated a variety of aerobic and resistance activities accommodating individual differences in physical activity interests (running and walking), and rarely link children's interests to team-games and sport activities [6, 7].

Current recommendations from select panels and national health organizations [12, 13] suggested that children should accumulate at least 60 minutes or more of aerobic moderate-to-vigorous intensity physical activity per day, and to perform muscle and bone-strengthening activities at least 3 days a week. Participation in activities that are age appropriate and enjoyable, and offer variety is recommended [13]. In Portugal, more than 60% of the children do not reach these recommendations [14]. Responsible factors for this low compliance are not well understood. A plausible explanation is probably linked to limited possibilities of undertaking recommended physical activity (type, duration, frequency and intensity) in many school and community settings. Another possible explanation is that children perceive prescribed PA as not enjoyable because it is superimposed by others and not self-chosen. Children tend to participate in relatively short bouts of physical activity. Heart rate (HR) monitoring demonstrates that recreationally active children perform primarily short bouts of activities (<5min) and seldom participate in long-sustained activities (>20min) [17].

By inference, physical activity proposed in intervention studies should closely represent the natural pattern of spontaneous physical activity among the children, thus increasing enjoyment of the participants. Soccer is one of the most popular, affordable, and widely practiced team-sports worldwide and has been recently suggested as a very effective "tool" in reducing CMRF in adults [16]. Traditionally played as 11vs11, but also conducted as small-sided games (3vs3, 5vs5), it is associated with relatively high energy expenditure and has a high aerobic component (HR>75max) [17]. Recreational soccer also involves high impact activities which stimulate the muscular-skeletal system [18]. The efficacy of a recreational soccer program on health and fitness of overweight children has been recently investigated [19, 20]. While no detailed CMRF were assessed, this novel data suggested that soccer has a high positive effect in weight control. Given this novelty, we believe that soccer being a highly popular sport, socially

and culturally meaningful and accessible to all social strata has an increased potential to operate as an effective “medicine” for the prevention of childhood obesity and CMRF.

Given this small number of studies that use soccer as a strategy to prevent childhood obesity, the next paragraphs intend to summarize the main results that are known about the effectiveness of physical activity programs on body composition, cardiorespiratory fitness, CMRF and inflammatory markers in overweight and obese children and adolescents.

Effect of physical activity on body composition and cardiorespiratory fitness

Table 1 summarizes the effects of physical activity interventions on body composition and cardiorespiratory fitness variables. Twenty-two studies quantified the impact of physical activity on BMI [7, 11, 28-46]. Fifteen of these studies were effective in reducing the BMI [7, 28, 30, 31, 33-40, 42, 46, 47], six studies did not report any significant change [11, 29, 32, 41, 43, 45], and only one study showed a BMI increase after the intervention [44]. Of the nineteen studies that measured the percentage of body fat [7, 11, 28-30, 32, 33, 35-40, 42-46], twelve studies have reported a decrease [28-33, 35, 37, 38, 40, 42, 43] and seven studies no change [7, 11, 36, 39, 44-46]. Nine of the 10 studies that measured waist circumference showed significant improvements after the intervention programs [7, 11, 31, 33, 38-40, 42, 43]. Only ten studies assessed changes in cardiorespiratory fitness [29, 31-35, 39-41, 43]. Seven of these studies showed an improvement in cardiorespiratory fitness [31-33, 35, 39, 40, 43], while three studies did not report any significant difference pre and post intervention program [29, 34, 41].

Effect of physical activity on CMRF

Table 2 exhibits the effects of physical activity interventions on blood pressure (BP) and heart rate (HR). Data on resting BP were available from ten studies [7, 29, 31, 33, 35-38, 43, 46]. Seven of the nine studies showed significant decreases in systolic BP (SBP) after the intervention [7, 29, 31, 33, 35, 43, 46], while three studies did not report significant changes [36-38]. Ten studies examined the diastolic BP (DBP) [7, 29, 31, 33, 35-38, 43, 46]. Three of them observed a reduction in their values [29, 35, 43], but the other seven did not report significant changes [7, 31, 33, 36-38, 46]. Only seven studies

measured the HR at rest or during submaximal exercise [11, 33, 34, 37, 38, 45, 46]. Four of them showed a reduction due to the intervention [11, 33, 34, 46], while the other three did not find significant differences [37, 38, 45].

Table 2. Effect of physical activity interventions on blood pressure variables.

Studies investigating the effects of physical activity on metabolic markers are shown in table 3. Of the twelve studies that measured insulin level [7, 11, 32, 33, 35, 36, 38-40, 43-45], six reported a decrease [7, 11, 32, 35, 39, 43] and seven did not detect significant changes [35, 36, 38, 39, 43, 45, 46]. Plasma glucose levels were measured in ten studies [11, 32, 35, 36, 38-40, 43, 44, 46], most of them reporting significant improvements. Nine studies examined the response of high-density lipoprotein cholesterol (HDL) to physical activity interventions and no significant change was reported [7, 35-38, 43, 44, 46]. However, of the seven studies that measured low-density lipoprotein cholesterol (LDL) levels [7, 35-38, 44, 46], four showed a significant decrease [7, 35-37], while three did not report significant changes [38, 44, 46]. Five studies showed a decrease in the total cholesterol level [7, 35-37, 39], but other five did not observe significant changes [29, 38, 44-46].

Table 3. Effect of physical activity interventions on metabolic variables.

Effect of physical activity on inflammatory markers

As shown in Table 4, few studies have investigated the effects of physical activity on inflammatory markers in overweight and obese children and adolescents. Of the seven studies that evaluated C-reactive protein (CRP) levels [7, 11, 28, 30, 38, 42, 46], three showed a reduction [28, 30, 42], three did not report significant changes [11, 38, 46] and only one study reported an increase after the intervention [7]. Five studies have examined the response of interleukin-6 (IL-6) to physical activity [11, 28, 30, 38, 42], three of them showing a significant decrease in their levels [28, 30, 42] and two reporting no significant change [11, 38]. Three studies evaluated the adiponectin levels [11, 38, 43], two of them detecting an increase in the basal levels [38, 43]. Among the two studies that measured the fibrinogen levels [7, 28], one reported a reduction [28], but one showed an increase after the intervention [7].

Table 4. Effect of physical activity interventions on inflammatory markers.

III. TASKS AND ACTIVITIES

In order to provide adequate answers to the above hypotheses, we proposed a timeline with several tasks and activities to develop throughout the project. Therefore, this report will present different tasks and activities implemented.

Table 5. Timeline with tasks and activities developed throughout the project.

3.1. TASK 1 - Contacts with CUF Hospital (Pediatric Unit) and Faculty of Sport administrations, parents and children

Activity 1 - Contacts with the CUF Hospital (Pediatric Unit) and Faculty of Sport administrations

The CUF Hospital and the Faculty of Sport of the University of Porto administrations were contacted to discuss the project, its importance and relevance in terms of Public Health and Education. During the meeting an extensive package with all information concerning the project was provided. In addition, it was discussed the timeline and involvement of the Pediatric Unit of CUF Hospital and Faculty of Sport in all the project phases.

Results achieved: Pediatric Unit of CUF Hospital and Faculty of Sport have authorized to conduct the project.

Resources allocated to this task: Material related to secretarial work.

Date of task conclusion: May 31th, 2013

Activity 2 - Contacts with the parents and children. Sample selection

A total of 200 children from the Pediatric Unit of the CUF Hospital – Porto were invited for participation in this project. In order to be included in this study, children had to be between 8 to 12 years of age, and to have a BMI greater than CDC 95th percentile for sex and age-specific [48]. Children using a medication or with diagnosed medical conditions that would limit their ability to perform activities (e.g., cardiovascular disease, type I diabetes, renal insufficiency, liver disease) were excluded. Children who participated in a structured exercise, nutrition and/or weight loss program for at least 1 year prior to the study were also excluded. Of these 90 obese children agreed to participate. Sample size calculations were performed a priori for repeated measures ANOVA using the G*Power software 3.1.9.2. Hypothesizing an effect size (Cohen's d) of 1.0 [49] for a required power of 95% at p<0.05, a sample size of at least eighteen in each group was required. Therefore, a larger sample size should provide adequate power for detecting both differences.

This study was ethically reviewed and approved by the research committee of the Faculty of Sport of the University of Porto and by hospital authorities (#12/2013). It was conducted in compliance with the declaration of Helsinki. All participating children and their legal representatives received information sheets and filled out written consent forms.

Results achieved: Parents and ninety children followed in the Pediatric Unit of CUF Hospital Porto gave their authorization consents agreed to participate in this study.

Resources allocated to this task: Material related to secretarial work.

Date of task conclusion: June 30th, 2013

3.2. TASK 2 - Baseline data collection, entering data, screening, statistical analysis and randomization of the intervention groups

Activity 1 - Baseline data collection

The evaluation of the children participating in this project required the completion of two assessments (baseline and final). The baseline assessment was conducted in the first week of September 2013 to all participating children at the Faculty of Sport - University of Porto. The final assessment was conducted in the first two weeks of March 2014 to all participating children at the Faculty of Sport - University of Porto. The methodology of this project, although very diverse, focused on seven major areas: (1) anthropometry; (2) body composition; (3) biological maturity status; (4) CMRF; (5) cardiorespiratory fitness; (6) perceived psychological status; (7) physical activity and dietary intake. Each child was tested on two occasions. Anthropometric and body composition measures, CMRF, and psychological measures were assessed during the initial visit whereas cardiorespiratory fitness was assessed during the second visit.

(1) Anthropometry

Body mass, height and waist circumference were measured following standardized procedures. Body mass was measured using a physician's digital scale (Tanita®, BC-418MA, USA) and height using a fixed stadiometer (Holtain Ltd., UK) and waist circumference with a metallic tape (Holtain Ltd.). BMI (kg/m^2) was calculated. The

children were classified as obese if they had a BMI greater than CDC 95th percentile for sex and age-specific [48].

(2) Body composition

Body composition was measured by dual-energy X-ray absorptiometry (DXA) (Hologic QDR 4500A, Hologic Inc., Waltham, MA, USA), which segments the body into the 3 compartments of fat mass, bone mass, and fat-free mass. The equipment was calibrated according to the manufacturer's instruction and well-trained technician made the exams. Children were scanned in supine position and the scans were performed in high resolution. Bone mineral content (BMC) and density (BMD) were measured for the whole body and the lumbar spine (L1–L4) using standard protocols. The same investigator analysed all total body scans. The principles behind body composition analyses with DXA are explained elsewhere [50].

(3) Biological maturity status

Stage of pubic hair (PH) was the indicator of biological maturity status. Stage of PH based on the criteria of [51] was evaluated at clinical examination by a pediatrician experienced in the assessment of secondary sex characteristics.

(4) Cardiometabolic risk factors

After an overnight fast, between 8.00 and 10.00 a.m. at Faculty of Sport - University of Porto, blood samples were collected by venipuncture in EDTA containing tubes and processed within 2 hours of collection, from all participants at baseline and after six months. Aliquots of plasma were made and stored at -80°C until assayed. Analysis of baseline and follow up samples were performed in the same day. All blood samples were analyzed for fasting blood glucose (FBG), high-density lipoprotein-cholesterol (HDL-c), triglycerides (TRG), fasting insulin, adiponectin (Adip) , leptin (Lept), resistin (Resit), C-reactive protein (CRP), tumor necrosis factor alpha (TNF- α), and oxidized low density lipoprotein cholesterol (LDL-ox). TC and TRG concentrations were determined by enzymatic colorimetric tests (CHOD-PAP and GPO-PAP methods, Roche, respectively). HDL-c was measured using a specific enzymatic colorimetric test (Direct HDL cholesterol, Roche). Low-density lipoprotein-cholesterol (LDL-c) concentration was calculated using Friedewald formula [52]. The determination of circulating levels of glucose and insulin was performed by using routine automated technology (Roche). CRP was determined by a immunoturbidimetry test (Roche). The degree of

insulin resistance was estimated with the use of the homeostatic model assessment for insulin resistance (HOMA-IR) and calculated as the product of the fasting plasma insulin (μ U/ml) and the fasting plasma glucose (mg/dl) divided by 405 [53]. Plasma concentration of Adip, Lept, Resist (e-Bioscience) and LDL-ox (Mercodia) were evaluated by commercial enzyme-linked immunoassays (ELISA). Blood samples were collected by qualified nurses of CUF Hospital. Breakfast was provided to all children immediately following sampling in the Faculty.

Resting blood pressure (BP) was determined using a digital sphygmomanometer (OMRON M6) after subjects had been seated for 10 min of rest. Two measures were taken with a 3-min interval between successive measurements. If the difference between the first and second measurement, either diastolic blood pressure (DBP) or systolic blood pressure (SBP), are greater than 10mmHg, a third measurement was taken. Children were classified according to sex, height and age-specific charts.

(5) Cardiorespiratory fitness

To assess the maximal oxygen uptake ($VO_{2\text{max}}$), all children were submitted to a continuous progressive treadmill exercise. Children were instructed to walk/run until exhaustion, according to a standardized exercise protocol [54, 55]. The exercise protocol started at 4km/h without inclination and maintained for 3 min so that children could adapt to the treadmill. After 3 min, speed was increased to 8km.h⁻¹. When 5 min were completed, the inclination was raised to 3%. After 7 and 9 min, the inclination was increased to 6% and 9%, respectively. If children were able to endure more, the speed was increased to 9 km/h after 1 min and then 10 km/h after 13 min.

(4) Perceived psychological status

A reduced version of the children's attraction to physical activity scale (CAPA) developed by Brustad [56] was utilized to measure interest in engaging in physical activity. The Portuguese-language version includes 14 items designed to measure the extent of children's interest in engaging in physical activity. The CAPA includes five dimensions of attraction to participation in physical activity including attraction to participate in vigorous physical activity; perceived importance of participating in physical activity; liking of games and sports; assessments of whether physical exertion is perceived to be fun or important; and attraction due to perceived peer acceptance in games and sports. The CAPA was scored on a 4 point format (one to four) using a "structured-alternative" [57]

approach. Children were presented with two opposing choices and asked to decide which statement best reflected their own feelings. This format was used as a means of reducing “social desirability” tendencies that often occur in responses of children to questionnaires. Once children made their choice, they then had select if it was “somewhat true” or “really true”.

Body image was examined using Collins’ child figure drawings scale [58]. The scale includes seven silhouette figures of boys and girls ranging from very thin to obese. The children were asked to indicate the figure that best represented how they currently looked (perceived) and how they wanted to look (ideal). Body dissatisfaction was the difference between the perceived and ideal scores. Negative and positive scores indicated a desire to be fatter or thinner respectively. Moderate to high test-retest reliability and validity have been previously shown for the scale in children [59].

Self-esteem was measured using Rosenberg’s self-esteem scale [60]. The responses to the 10 items were rated on a 4-point scale (strongly disagree to strongly agree), yielding scores between 10 and 40, with higher scores indicating higher self-esteem. This scale is the most widely used measure of global self-esteem and is valid and reliable for students in third to eighth grades [61].

The self-perception profile for children [62] was also used to assess children’s perceived self-competence. The scale is composed of five specific self-concept domains (scholastic competence, athletic competence, social competence, physical appearance, and behavioral conduct) and a separate global self-worth (or self-esteem) subscale. There are a total of 36 items, six for each subscale. The response to each item is scored from 1 to 4, where a score of 1 represents a low perceived competence and a score of 4 indicates a high perceived competence. The response scale is presented in a structured alternative format in order to overcome the children’s tendency to give socially desirable responses. For each statement the child is first asked to decide which kind of kids he/she is most like, those described on the left or those described on the right. Once having made this decision, the child next decides one of these options “really true for me” or “sort of true for me”.

The pediatric quality of life inventory version 4.0 [63] was used to assess health-related quality of life. It is based on a modular approach with generic and disease-specific

instruments. The generic core scales were specifically designed to measure the core health dimensions outlined by the World Health Organization, covering physical, emotional, social and school functioning. For children ages 8-18 years, items are rated on a 5-point likert response scale, ranging from 0 (never) to 4 (almost always), to indicate how much the child has problems with these areas of functioning. From these four core scales, three summary scores can be calculated: a total quality of life score, a physical health score, and a psychosocial health score (emotional, social, and school functioning scales combined).

(7) Physical activity and dietary intake measures

Daily PA was measured using an ActiGraph accelerometer, model GT3X (Pensacola, FL USA) at the baseline and at the conclusion of the study. This is a small, lightweight, triaxial device. This accelerometer produces “raw” output in activity counts per minute (cpm), which gives information about the total amount of physical activity [64]. The accelerometer output can also be interpreted using specific count cut-points, which categorizes activity counts as either sedentary, light, moderate, or vigorous PA. Data reduction, cleaning, and analyses of accelerometer data were performed as described elsewhere [65, 66]. For the present study, data were analyzed using specific cut-points, which have been validated for children and adolescents: ≥ 2296 cpm for moderate to vigorous PA [67]. In this study, the epoch duration was set to 5 seconds, which seems to be more accurate and suitable concerning to the spontaneous and intermittent activities of the young children [68]. The study was conducted on 7 consecutive days (Monday to Sunday). A minimum of 10 hours per day was considered as valid data for the analysis. Parents were instructed to attach the accelerometer when the child awoke and to remove it when they went to bed. The accelerometer was firmly adjusted at the child’s hip by an elastic waist belt under their school clothing. Activities were not prescribed or directed by the teachers or researchers. All children participated in normal activities with their classmates.

Dietary intake was assessed at the baseline and at the conclusion of the study from a three-day dietary record, including two weekdays and one weekend day, completed by parents. Foods portion size and beverages consumed were estimated using household measures (cups, glasses, spoons, slices, food wrappers or containers etc.) as an aid in determining serving sizes. A description of each food and beverage consumed was recorded, including the method of preparation, the time (to the nearest 5 minutes),

location and if appropriate the brand name of the product. The nutrient analysis was performed using the software Food Processor SQL (ESHA Research Inc., Salem, OR, US). This program uses nutritional information from the United States that has been adapted for use with typical Portuguese foods and beverages. Nutrient means of the three days was used in the analysis. At enrollment all children had a meeting with a nutritionist where appropriate food choices were discussed such as the reduction intake of energy dense foods by substituting by healthier alternatives and the increase consumption of fresh fruits and vegetables. Furthermore, one hour session in a small group was led by a nutritionist about energy balance and healthy diet concepts.

Results achieved: Baseline data in all items of the study were collected.

Resources allocated to this task: materials related to secretarial work (questionnaires), breakfast food (bread, ham, cheese, yogurt, and water), material and equipment to blood analysis (specific kits conceived in specialized laboratories).

Date of task conclusion: September 8th, 2013

Activity 2 - Entering data, screening and statistical analysis

After data collection, it was entering data, screening and statistical analysis. Descriptive statistics (means and standard deviations) were calculated for both groups at the baseline. None of the anthropometric, body composition, CMRF, inflammatory markers, cardiorespiratory fitness and psychological measures showed significant deviations from a normal distribution (Kolmogorov-Smirnov normality test). Baseline differences in mean anthropometric, body composition, CMRF, cardiorespiratory fitness and psychological characteristics between groups were tested with one-way analysis of variance (ANOVA) and chi-square tests (biological maturity status). Effect size was calculated using partial eta-squared (η^2) and interpreted as small (≥ 0.01), medium (≥ 0.06), or large (≥ 0.14) [49]. The significance level in all analyses was set at 0.05. Statistical analyses were conducted using SPSS version 21.0.

An individual report including all test results and a brief interpretation were provided to the children's parents (see appendix).

Results achieved: at the end of this task it was obtained all the baseline information needed, data entry, screening and statistical analysis.

Resources allocated to this task: Two graduate students in Sport Sciences, under the guidance of the principal investigator were selected to punching and screening data.

Date of task conclusion: September 8th, 2013

Activity 3 - Randomization of the intervention groups

After completing the baseline measures, data entering, screening and statistical analysis, ninety children were randomly assigned to different training groups: the first group was designated has the soccer group (SG) (n=30); the second group has the traditional physical activity group (TG) (n=30); and the third group comprised children who were not interested to participate in any intervention and whose physical activities were limited to those included in the compulsory physical education curriculum at school and was defined as control group (CG) (n=30) (2 sessions per week, 45-90 min each). Children were assigned to intervention groups on the basis of the day of the week in which they have the possibility to attend the training sessions. Children who attended on tuesday, thursday and saturday were assigned to the SG and those on monday, wednesday and friday to the TG. Figure 1 provide a detailed schematic of the study design and children flow.

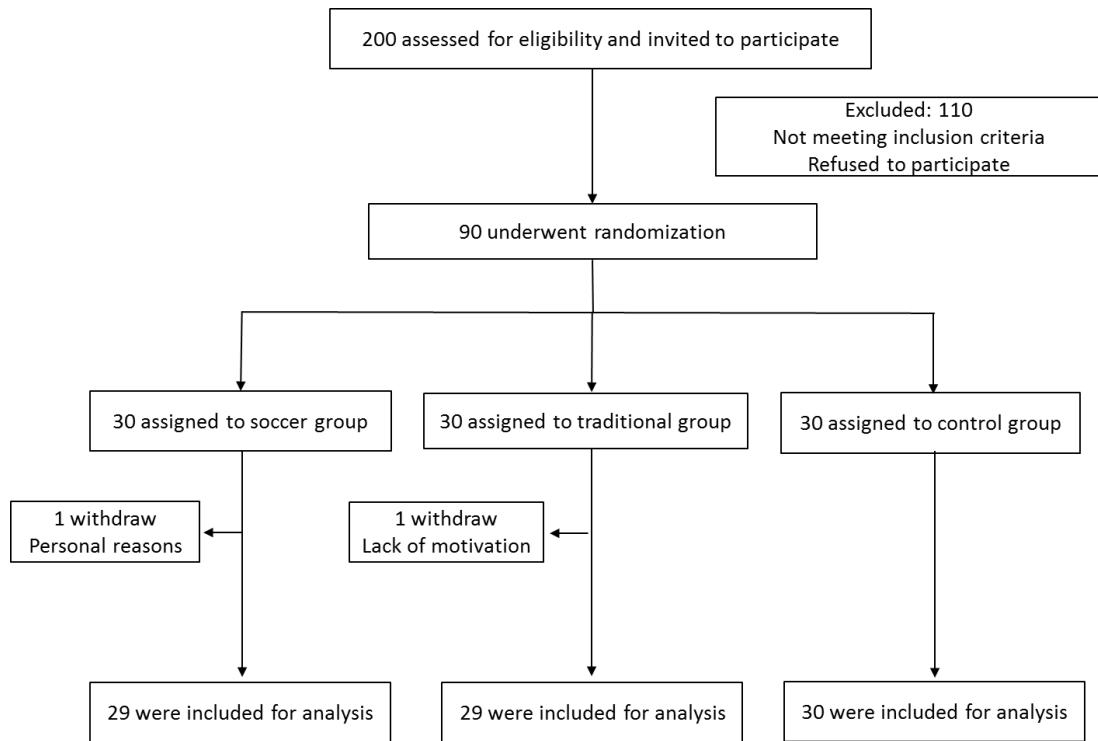

Figure 1. Participant flow diagram.

Results achieved: randomization of the intervention groups.

Resources allocated to this task: Principal investigator.

Date of task conclusion: September 8th, 2013

3.3. TASK 3 - Soccer and individual intervention programs

Activity 1 - Soccer and traditional intervention programs

The soccer intervention program consisted of a warm-up (10-20 min), different technical drills and small-sided games (40-60 min), and a cool-down (10 min). The detailed contents and types of exercises of soccer intervention program is summarized in Table 6. The soccer intervention program was carried out at the facilities of the Faculty of Sport - University of Porto three times a week (tuesday and thursday, 18:30-20:00 hours; saturday, 10:00-11:30).

Table 6. Contents and types of exercises of soccer intervention program.

Contents	Types of Exercises
Tactical - Technical	
Individual tasks	1st Phase - small sided games (1v0; 2v0; 3v0+Gk; 1v1+Gk)
Passing	
Reception	
Shooting	2nd Phase - attack v defense (2v1+Gk; 2v2+Gk; 3v2+Gk; 4v3+Gk; 6v5+Gk)
Dribbling	
Intercept	
Basic marking/ Open-up	3rd Phase - small sided games (Gr+3v3+Gr; Gk+4v4+Gr; Gk+6v6+Gk)
Elementar Collective tasks	
Defensive and offensive principles	
Combinations	
Physical fitness	
Aerobic	Games and drills with and without ball
Anaerobic	
Muscular strength	
Coordination	
Agility	
Flexibility	

The traditional intervention program was multidimensional, since it was designed to develop aerobic endurance, strength, flexibility, coordination and balance. In each session we try to provide routines with activities and exercises as varied as possible, in accordance with the recommendations of [12]. The physical activity program was also designed to develop the enjoyment and body awareness, looking to long-term changes in behavioural patterns. All sessions consisted of a generalized type of physical activity that is usually offered to this age group and that include: a warm-up (10-20 min), different kind of activities such as walking, running, gymnastics, and exercises to improve coordination, flexibility, and strength training (40-60 min), and cool-down (10 min). The traditional physical activity intervention program was carried out at the facilities of the Faculty of Sport - University of Porto three times a week (monday, wednesday and friday, 18:30-20:00 hours).

The training intensities for both intervention programs were designed to keep the heart rate (HR) > 70-80% of maximum heart rate as confirmed by heart rate monitoring (Polar

Team 2 Pro System, Polar Electro, Kempele, Finland). The training sessions were conducted by two physical education teachers. Both intervention programs training sessions were supervised by two graduates in Sport Sciences, under the guidance of principal investigator. Both intervention programs were initiated on September 9th, 2013 and finished on March 9th 2014. In the first two weeks of March 2014 were held the final assessments.

Children that composed the CG did not have any intervention and followed the compulsory physical education curriculum at school (n=30) (2 sessions per week, 45-90 min each).

Results achieved: To conclude soccer and traditional intervention programs.

Resources allocated to this task: Two physical education teachers, under the guidance of the principal investigator, supervised intervention programs training sessions.

Date of task conclusion: March 9th, 2014

3.4. TASK 4 - Post intervention data collection, entering data, screening and statistical analysis

Activity 1 - Final data collection

Post intervention data collection was structured in the same manner as baseline assessment.

Results achieved: Post intervention data in all items of the study were collected.

Resources allocated to this task: materials related to secretarial work (questionnaires), breakfast food (bread, ham, cheese, yogurt, and water), material and equipment to blood analysis (specific kits conceived in specialized laboratories).

Date of task conclusion: March 16th, 2014

Activity 2 - Entering data, screening and statistical analysis

After post intervention data collection, we started data entry, screening and statistical analysis. Descriptive statistics (means and standard deviations) were calculated for both groups at the conclusion of the study. None of the anthropometric, body composition, CMRF, inflammatory markers, cardiorespiratory fitness and perceived psychological measures showed significant deviations from a normal distribution (Kolmogorov-Smirnov normality test). The intervention effects were evaluated with, a repeated measures analysis of variance (ANOVA). For each characteristic, percentage of change ($\% \Delta$) between baseline and after 6-months was also calculated; the difference was then divided by baseline value. Pearson correlation coefficients were calculated to examine which CMRF and inflammatory markers were associated with BMI z-score, percentage of body fat and WtHR at the baseline and at the conclusion of the study. The significance level in all analyses was set at 0.05. Statistical analyses were conducted using SPSS version 21.0.

Results achieved: at the end of this task it was obtained all the post intervention information needed, data entry and statistical analysis. For financial reasons three inflammatory and oxidative markers (grelin, IL-6 and TBARS) were not determined. However, many others, such as oxLDL, CPR, leptin, resistin, adiponectin and TNF- α were determined.

Resources allocated to this task: Two graduate students in Sport Sciences, under the guidance of the principal investigator were selected to data entry and screening data.

Date of task conclusion: March 24th, 2014

3.5. TASK 5 - Main Findings

Adherence

Of the 90 children participants in this project, 88 completed their assigned intervention. Two children (one each in SG and TG) did not complete the study because of personal reasons (SG) and lack of motivation (TG) (Figure 1). An average of 72 sessions were conducted in each intervention group. Adherence measured by the number of sessions attended during the intervention programs was higher >85% for both groups. The

average training durations and heart rate (HR) were similar between the SG (84.4 ± 6.5 min/session; 156.3 ± 6.4 bpm, $\approx 78\%$ HRmax) and TG (80.1 ± 8.3 minutes; 155.3 ± 7.8 bpm, $\approx 75\%$ HRmax).

Baseline differences

There were no significant differences between groups for baseline variables ($p > 0.05$) (Table 7).

Table 7. Baseline characteristics of participants by intervention assignment.

Intervention effects on anthropometric characteristics, body composition, CMRF and inflammatory markers, cardiorespiratory fitness and psychological status

Changes in anthropometric characteristics, body composition, CMRF and inflammatory markers, cardiorespiratory fitness and psychological measures in each group are shown in Tables 8 to 10.

Anthropometric characteristics and body composition

- Children involved in physical activity intervention programs decreased significantly their BMI z-score, fat mass, percentage of body fat, WC and WtHR ($p<0.05$) and increase their muscle mass, BMC and BMD z-score ($p<0.05$).
- Children participants in the CG only showed a significant improve in muscle mass and BMC between baseline and the end of the study ($p<0.05$). In contrast, a significant increase in fat mass and percentage of body fat was observed ($p<0.05$).

CMRF and inflammatory markers

- SG showed appreciable decreases in total cholesterol, HDL cholesterol, LDL cholesterol, and DBP ($p<0.05$).
- Triglycerides decreased significantly in the two groups involved in sport activities ($p<0.05$).
- Changes in SBP, glucose levels, insulin and HOMA-IR were not significantly different between groups ($p>0.05$).
- Leptin decreased significantly in the two groups involved in sport activities ($p<0.05$).
- Resistin and oxLDL decreased significantly in the SG ($p<0.05$).
- Adiponectin concentrations improved in both groups ($p<0.05$), with a greater increase in the two groups involved in sport activities (SG: 23.6%; TG: 19.4%).
- Circulating concentrations of CRP decreased in children in both intervention groups ($p>0.05$).

Psychological measures and cardiorespiratory fitness

- Significant greater changes was observed in perceived psychological status in both intervention groups compared to CG.
- Children involved in physical activity intervention programs improved their body image, self-esteem, and quality of life, perceived themselves as more successful and physically competent, and were more attracted to participate in PA ($p<0.05$).

Association between CMRF and inflammatory markers and BMI z-score, percentage of body fat and WtHR

The association between CMRF and inflammatory markers and BMI z-score, percentage of body fat and WtHR in each group are shown in Tables 11 to 13.

- Leptin concentrations were significantly associated with BMI z-score, percentage of body fat and WtHR in both groups at the conclusion of the study ($p<0.05$).
- CRP was positively associated with percentage of body fat in both groups at the conclusion of the study ($p<0.05$).
- Adiponectin was negatively associated with BMI z-score, percentage of body fat and WtHR in children participants in the CG at the conclusion of the study ($p<0.05$).
- oxLDL was positively associated with BMI z-score and WtHR in children participants in the CG ($p<0.05$).

Given the enormous interest that the Portuguese public opinion and academic community has shown with regard to this project, we will organize on 4 to 5 of June 2014 an international conference on “Soccer as a strategy to promote health and quality of life”. The idea is to inform and discuss that Soccer can be an important strategy for promoting health and quality of life, regardless of nutritional status, age, sex, socio-economic status and ethnicity of their participants.

In addition to the presentations of the team members associated with this project, other Portuguese and International academic researchers and personalities related with soccer were also invited to present a communication. It would be a great honor for us to have the UEFA participation in this conference with the presentation of a lecture on a topic related to Soccer and Health. As soon as possible we send you a preliminary program of this conference.

Conference date: June 4th and 5th, 2014

V. CONCLUSIONS

Childhood obesity is associated with several adverse physical, cardiometabolic and psychological health consequences [69, 70]. The potential of physical activity interventions to alleviate the burden of obesity and to improve the weight status, body composition and cardiometabolic and perceived psychological status of obese children is thus significant to public health. The present study was designed in this context and specifically examined the effects of a 6-month recreational soccer intervention program on the body composition, cardiometabolic risk factors (CMRF), inflammatory markers, perceived psychological status and cardiorespiratory fitness (CRF) of obese children.

The first research hypothesis addressed in the study was the following:
“Systematic practice of recreational soccer has a significant effect in reducing CMRF and percentage of body fat, and in improving muscle and bone mass, cardiorespiratory fitness and associated psychological consequences”.

The 6-month recreational soccer intervention program (60-90 min, three times per week, intensity >70-80% HRmax) resulted in beneficial changes in body composition, CMRF, inflammatory markers, perceived psychological status and CRF of obese children.

The soccer intervention program showed a positive effect on all parameters of body composition and nutritional status. After the 6-month intervention, participants in the soccer intervention experienced significant reduction in percentage of body fat (-7.4%), and improvement in muscle (+7.3%) and bone mass (+5.5%), with negligible change in BMI (-1.1%). In addition, WC (-5.3%) and WtHR (-4.2%) declined. The latter indicators are highly predictive for CMRF [71]. There is strong evidence that beneficial effects on muscle and bone mass may be achieved by promoting participation in high impact sports, which impose high levels of muscular contractions and submit the growing skeleton to frequent mechanical stresses and strains [72-74]. Soccer is an activity that activates a wide range of the body's musculature to meet the physical demands of the game, such as numerous changes of the speed running, kicking the ball and body contacts [75]. Further, since soccer involves a high number of jumps and other movements requiring abrupt changes of the position of the body center of mass, it can be considered a weight-bearing sport [75]. Results of the present study reinforce these concepts and highlight the positive contribution of soccer to augment muscle (+7.3%) and bone (+5.5%) mass.

Beneficial effects of regular physical activity on CMRF, inflammatory markers and CRF are well-established in obese children and adolescents [7, 28, 32, 33]. Most of the studies have used traditional endurance activities (walking, jogging or bicycling) and occasionally group activities. To our knowledge, no studies have addressed the effects of an intense intermittent soccer intervention on CMRF, inflammatory markers and CRF in obese children. Findings of the present study indicated significant improvements in CMRF (-28.9% to 5.7%) and inflammatory markers (-132.4% to 23.6%) and also CRF (+11.6%) over the course of the soccer intervention program.

The soccer intervention program was also associated with beneficial changes in psychological status in obese children. SG participants experienced significant improvements in body image, self-esteem, attraction to participate in PA,

perceived physical competence and quality of life. The results were consistent with other studies highlighting the importance of physical activity in enhancing perceived psychological status of obese children [8, 79]. The present findings thus suggested that participation in soccer was an effective strategy to reverse and perhaps enhance perceived psychological status associated with obesity in late childhood/early adolescence (8-12 years). The results also suggested an increase in the likelihood of the adoption and maintenance of physical activity among the soccer participants [80]. In addition to these aspects is important to note that soccer is the most popular and preferred sport at all ages and across social and economic strata of the population [81]. Since soccer is a relatively inexpensive, accessible, and easy sport to learn, it may offer obese children opportunities for enjoyable physical activity that has potential psychological benefits. As a team-based activity, soccer probably has more chances to enhance perceived psychological status of participants than many individual physical activities. The team/group format includes teammates (peers) who provide encouragement and also who serve as a buffer when things break down during game play. In contrast, it is suggested that participation in most forms of individual activities/sports provides limited interactions with other youth. Individual activities also encourage the development of a strong sense of mastery or individual accomplishment whereas team sports provide a fertile ground for self-esteem enhancement associated with the group nature of the activities. Team activities also provide opportunities for children to engage with peers and adults in an effort to achieve collective goals (39). Other research has also noted that children involved in team sports reported greater body satisfaction than children participating in individual activities (40). Since team activities/sports focus on the group in contrast to the individual, they may provide a buffer to individual social evaluation as the focus is on the group. Individual activities/sports, in contrast, offer more opportunities for one-on-one comparisons, which may heighten levels of body dissatisfaction (40). Thus, soccer appear to have the potential to promote teamwork and sharing, and provide opportunities to enhance attraction to participate in physical activity, self-esteem, self- and body-satisfaction, perceived physical competence and quality of life.

In summary, the soccer intervention resulted in significant improvements in body composition, CMRF and cardiorespiratory fitness and perceived psychological

status of obese children. Soccer as a highly popular sport, socially and culturally meaningful and accessible to all social strata thus has potential to operate as a highly effective tool for the prevention and reduction of childhood obesity and associated consequences for health and fitness.

The second research hypothesis addressed in the study was the following: "Systematic practice of recreational soccer has a greater effect than other traditional physical activity intervention program in increasing energy expenditure, reducing CMRF, and improving body composition, cardiorespiratory fitness and associated psychological consequences".

To our knowledge, this study may be the first which compared a soccer intervention (SG) with a traditional physical activity program (TG) and a control group (CG). The three groups did not differ in lipid profile, markers of glucose metabolism, inflammatory markers, CRF, and indicators of psychological status at baseline.

After the 6-month intervention period, CG showed significant changes in body composition, specifically an increase in body fat, fat mass, muscle mass and BMC, but no significant changes in lipid profile. Rather, the trend in means suggested a worsening of the lipid profile (except for HDLc), inflammatory markers (increased CRP and TNF- α), oxidative stress (higher oxLDL) and glucose metabolism (increased insulin, HOMA-IR, resistin; decreased leptin). In contrast this pattern was almost reversed in SG and TG who presented a general improvement in the body composition and CMRF profile compared to the CG. This improvement, however, was more apparent in SG than TG.

Obese and sedentary individuals often present a more atherogenic lipid profile than non-obese and physical active individuals. In the present study, physical activity, as in SG and TG, was associated with improvements in plasma lipids (reduced TC, LDL-c, oxLDL; increased HDL-c) and reductions in triglycerides. The results for oxLDL are of particular relevance, as oxidized LDL particles play a major role in the formation of atherosclerotic plaques. The reduction in oxLDL and triglycerides together with an increase in HDL-c is associated with a slowing of the atherogenic process.

Obesity is often described as a state of chronic low grade inflammation, characterized by an increase in pro-inflammatory mediators and a reduction in anti-inflammatory defenses. SG and TG both presented a decrease in the pro-inflammatory mediator leptin, a marker of adiposity and insulin resistance, and an increase in adiponectin, an anti-inflammatory mediator associated with positive changes in insulin sensitivity, lipid profile and oxidative stress. Both groups also showed a reduction (only statistically significant in the SG) in the acute-phase protein CRP, a sensitive marker of inflammation and of cardiovascular risk. SG group also showed a reduction in resistin, a mediator traditionally linked to insulin resistance.

Insulin resistance is a major issue in obesity, and is associated with dyslipidemia and increased inflammation and oxidative stress. Although changes in markers of glucose metabolism (glucose, insulin and HOMA-IR) were not significant, the data suggested an increase in insulin sensitivity (reduction in insulin and HOMA-IR) in both SG and TG in contrast to CG. The improvement in insulin resistance is consistent with the observed increase in adiponectin and the reduction in leptin and resistin. These results may have contributed to the favorable changes observed in the lipid profile.

The present study showed that both physical activity interventions (SG and TG) were effective in improving cardiorespiratory fitness and psychological status. Significant improvements in $\text{VO}_{2\text{max}}$ occurred in both intervention groups. Participants in the SG experienced an 11.6% improvement in $\text{VO}_{2\text{max}}$ and a 1.4 to 10.1% improvement in their psychological status whereas participants in the TG group experienced a 9.7% and a 0.9 to 10.3% improvement in both the $\text{VO}_{2\text{max}}$ and psychological status. Evidence suggests that lower cardiorespiratory fitness has been associated to an increase in CVD risk markers, CVD morbidity and mortality. To oppose this evidence, international health organizations suggest that children should accumulate at least 60 minutes or more of aerobic MVPA per day [12]. The recommendations also specify that the MVPA should be developmentally appropriate and enjoyable, and should include a variety of activities. Although the duration of the both intervention programs implemented in the present study (60-90 min, 3 times/week) were less than current recommendations, it seems that the intensity (average intensity >70-80%HRmax) were appropriate to induce significant improvements in cardiorespiratory fitness.

It is important to note that obese children complied well with the both intervention programs, resulting in high attendance rates (>85%). For all these reasons, present study demonstrates the potential of both interventions as a means of improving cardiorespiratory fitness and psychological status in obese children. However, given that soccer is a highly popular sport, relatively inexpensive, accessible, and easy to learn may be a better mode of exercise for obese children of this age group.

In summary, the two physical activity intervention groups (SG and TG) showed improvements in lipid profile, insulin sensitivity, inflammatory status, cardiorespiratory fitness and psychological status compared to the control group (CG). The improvement in some variables was more apparent in SG than TG.

The third research hypothesis addressed in the study was the following: “With recreational soccer as the template for regular physical activity or reducing the expression of CMRF, new subsets of markers with greater sensitivity and predictive and clinical utility will be developed”.

Cardiovascular morbidity and mortality of obesity is associated with classic risk factors, namely dyslipidemia, hypertension and impaired glucose metabolism [22]. However, classical markers may not be sufficiently sensitive at pediatric ages and highlight a need to consider other markers of CMRF. Recent research suggested the existence of other biological markers associated with pro-inflammatory and pro-oxidant states which are expressed at earlier ages with greater sensitivity [24, 25]. These novel markers are adiponectin and its isoforms, leptin, resistin, high sensitivity C- reactive protein (CRP), tumor necrosis factor alpha (TNF- α) and lipoprotein particularly its oxidized high-density (LDL-ox).

Previous studies examining the association between CMRF and obesity and body composition components in children have reported conflicting results. However, some of them have reported positive or negative associations and others have reported no associations. The results of the present study showed a significant and positive association between leptin concentrations and BMI z-score, percentage of body fat and WtHR. High levels of leptin were associated with an increase in obesity and percentage of body fat in obese children. Leptin

acts in the hypothalamus and helps to control energy intake and expenditure in lean individuals. In obese, however, a state of resistance to leptin actions (similar to what occurs for insulin) appears, leading to an increase in its circulating levels [83]. The absence of leptin increases appetite and decreases energy expenditure, leading to obesity. Many previous studies have discussed the effects of regular physical activity on leptin concentrations [84-85], but uncertainty remains as to how circulating leptin reacts to exercise training since previous studies have produced inconsistent results. However, the results of the current study showed a 60 to 66.9% decrease in leptin levels among children who participated in physical activity intervention programs suggesting that obese children can decrease leptin production and secretion in response to physical activity participation and subsequent changes in body composition.

Another important finding was the inverse association between adiponectin levels and BMI z-score, percentage of body fat and WtHR that was observed in the CG participants at the conclusion of the study. Lower levels of plasma adiponectin were significantly associated with obesity and body composition components in the obese CG participants. Adiponectin is an adipocytokine with multiple positive effects on metabolism, such as regulation of satiety carbohydrate and lipid metabolism, increasing insulin sensitivity and reducing oxidative stress, inflammation, atherogenesis and vascular remodeling [26]. Obesity increases the production of adipocytokines that cause insulin resistance but decreases the production of adiponectin, which reduces insulin resistance [82]. Previous studies examining the effects of exercise training on adiponectin levels have also reported conflicting results

Although previous studies have shown that adiponectin levels seems to be already reduced in young obese subjects the effects of physical activity in their production and secretion have reported conflicting results. The present study demonstrated that physical activity induce significant improvements in adiponectin levels among obese children.

In summary, although more studies are needed to understand the association between CMRF and inflammatory markers and obesity, the use of leptin and adiponectin in routines clinical analyses could help to identify children with increased risk of obesity and obesity-associated comorbidities.

The TAKE HOME MESSAGE of the present study was the following: "Soccer as a highly popular socially and culturally meaningful sport accessible to all social strata is a highly effective medium for the prevention/reduction of childhood obesity and for the enhancement of body composition, cardiometabolic health, cardiorespiratory fitness and associated psychological status of obese youth".

Pratica Atividade Física organizada fora da escola? Sim Não

Se Sim, qual/quais:

<u>Tipo de Atividade</u>	<u>Nº de vezes por semana</u>	<u>Duração de cada sessão</u>	<u>Dia(s) da semana</u>
	1x 2x 3x 4x 5x 6x 7x	30` 45` 1h 1h30	
	1x 2x 3x 4x 5x 6x 7x	30` 45` 1h 1h30	
	1x 2x 3x 4x 5x 6x 7x	30` 45` 1h 1h30	

Exemplo:

Karaté 1x 2x 3x 4x 5x 6x 7x 30` 45` 1h 1h30 Segunda e Sexta

Qual o transporte que utiliza para ir para a escola?

carro autocarro mota a pé Outro: _____

quanto tempo demora no percurso casa-escola? _____ minutos

Qual o seu tipo de habitação:

apartamento moradia Outro: _____

No local onde vive, é possível que o seu filho brinque no exterior? SIM NÃO

Se Sim, onde? na rua num parque junto à sua casa no quintal/jardim de casa no parque infantil

Se não, qual o motivo? não tem quintal/jardim em casa a rua tem muito tráfego não há parque infantil

a rua é perigosa em termos criminais, Outro: _____

	NUNCA	RARAMENTE	OCASIONALMENTE	FREQUENTEMENTE	SEMPRE
o meu/minha filho/a é naturalmente muito ativo	<input type="checkbox"/>				
o meu/minha filho/a precisa de mim para ter motivação para brincar	<input type="checkbox"/>				
o meu/minha precisa de companhia (amigos, Irmãos, pais) para ter motivação para brincar	<input type="checkbox"/>				

Comparando com crianças da mesma idade, considera o seu/sua filho/a:

- MUITO MAIS ACTIVO
- MAIS ACTIVO
- IGUAL
- MENOS ACTIVO
- MUITO MENOS ACTIVO

O/A seu/sua filho/a com quem vive: PAI MÃE IRMÃOS AVÓ AVÔ OUTROS: _____

Quantas horas por dia, o/a seu/sua filho/a passa na escola? |_____|Horas |_____|Min

Quantos televisores têm em sua casa? 1 2 3 4 >4

O seu/sua filho/a tem televisão no quarto? SIM NÃO

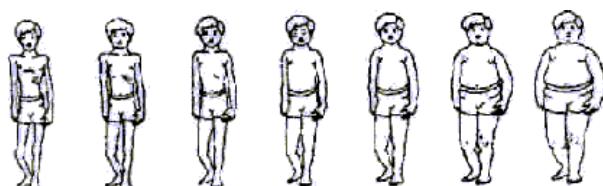

Tem computadores (fixos e portáteis) em sua casa? SIM NÃO **Se sim, quantos** _____

Tem videojogos (nitendo, playstation, wii, gameboy) em sua casa? SIM NÃO **Se sim, quantos** _____

Durante as refeições a televisão está ligada e a atenção está centrada na televisão? SIM NÃO

Acha que seu filho tem, neste momento, um Peso Muito Baixo Baixo Ligeiramente Magro Normal
 Ligeiramente com excesso de peso Excesso Peso Obesidade

Qual destas figuras é semelhante ao seu filho(a)?

1 2 3 4 5 6 7

1 2 3 4 5 6 7

(COLOQUE UM CÍRCULO NO NUMERO QUE SE ENCONTRA ABAIXO DA FIGURA ESCOLHIDA)

Organização do Sono (BISQ)

Por favor, coloque apenas uma resposta (a mais apropriada) em cada questão.

O seu filho/a dorme: em quarto próprio no quarto dos pais na cama dos pais
 em quarto partilhado com o irmão(s) OUTRO: _____

Em que posição o seu filho/a dorme a maior parte do tempo? de barriga para baixo de lado de costas

Quanto tempo o seu filho/a dorme durante a NOITE (entre as 19h da tarde e as 7h da manhã)?	_____ ____ Horas _____ ____ Min
Quanto tempo o seu filho/a dorme durante o DIA (entre as 7h da manhã e as 19h da tarde)?	_____ ____ Horas _____ ____ Min
Quanto tempo durante a noite o seu filho/a está acordado (entre as 22h da noite e as 6h da manhã)?	_____ ____ Horas _____ ____ Min
Quanto tempo é que o seu filho/a demora a adormecer?	_____ ____ Horas _____ ____ Min
A que horas o seu filho vai dormir?	_____ ____ Horas _____ ____ Min

Número de vezes o seu filho/a acorda por noite: ? nunca acorda 1 vez 2 vezes ≥3 vezes

Como é q o seu filho/a adormece? enquanto toma o biberão embrulhado com ajuda
 na cama sozinho na cama junto aos pais OUTRO: _____

Acha q o seu filho/a tem problemas de sono? problemas muito sérios
 pequenos problemas
 Não tem problemas

Escala de Regulação Emocional (ERRS)

Por favor, classifique o seu filho de acordo com as descrições abaixo, colocando um círculo no número mais adequado. O número 4 que está sublinhado no centro representa o ponto médio no qual a criança se poderá situar nesse item. Por favor esteja à vontade para usar todas as possíveis opções de resposta..

	Não é provável							Muito provável
	1	2	3	4	5	6	7	
1. Depois de receber de alguém um presente que não gosta, qual a probabilidade do seu filho fingir que gosta do presente?	1	2	3	<u>4</u>	5	6	7	
2. Depois de ver alguém tropeçar ou cair de uma forma engraçada, qual a probabilidade do seu filho rir à gargalhada?	1	2	3	<u>4</u>	5	6	7	
3. Depois do seu filho comer algo que lhe sabe mal, qual a probabilidade dele cuspir a comida ou reagir negativamente?	1	2	3	<u>4</u>	5	6	7	
4. Num contexto mais sério, como uma igreja ou um funeral, qual a probabilidade do seu filho entender e se comportar adequadamente à situação?	1	2	3	<u>4</u>	5	6	7	
5. Se lhe for pedido para guardar um segredo (p. ex., não falar ao irmão sobre a festa de aniversário surpresa), qual a probabilidade do seu filho manter o segredo?	1	2	3	<u>4</u>	5	6	7	
6. Qual a probabilidade do seu filho ajudar os outros (p. ex., amigo / irmão) a manter um segredo de forma a evitar um castigo? (p. ex., não contar à mãe que um irmão partiu um vaso)	1	2	3	<u>4</u>	5	6	7

QUESTÕES RELACIONADAS COM A GRAVIDEZ:

Idade que tinha quando engravidou do/da seu/sua filho/a? _____

Quantos filhos tem? _____ Que idade têm? _____

Recorde-se da alimentação do bebé no 1ºano de vida, durante quanto tempo foi amamentado, **só com leite materno?**

Não foi amamentado _____

Foi amamentado: quanto tempo: _____ dias ou _____ semanas ou _____ meses

Em que altura (dias, meses ou semanas), lhe introduziu **outro alimento**, além leite materno?
_____ dias ou _____ semanas ou _____ meses

Que alimento foi? (assinalar com uma cruz)

Leite de vaca Leite de lata Papas Sopa Outro: Qual? _____

Qual o seu peso no início da Gravidez do seu filho? _____ Kg e no final? _____ Kg

Quantos quilos no total, aumentou no seu peso, durante a gravidez? _____ Kg

Teve diabetes gestacional? Sim Não

Teve pré-eclampsia? Sim Não
(tensão arterial elevada)

Teve de alteração a sua alimentação durante a gravidez? Sim Não Se sim, motivo? _____

O/A seu/sua filho/a nasceu com quantos meses ou semanas de gestação: _____ semanas (**Ex: 38 semanas**)

Tipo de Parto? Parto Normal Cesariana

Fumou durante a Gravidez? Sim Não Se Sim, quantos por dia? _____

Manteve ou reduziu o consumo de tabaco? _____

ACTIVIDADE FÍSICA HABITUAL DOS PAIS

Questionário Internacional de Atividade Física (IPAQ)

As questões que lhes vou colocar, referem-se à semana imediatamente anterior, considerando o tempo em que esteve fisicamente ativo/a. Por favor, respondam a todas as questões, mesmo que não se considerem pessoas fisicamente ativas. Vou colocar-lhes questões sobre as atividades desenvolvidas na vossa atividade profissional e nas vossas deslocações, sobre as atividades referentes aos trabalhos domésticos e às atividades que efetuam no vosso tempo livre para recreação ou prática de exercício físico / desporto.

Ao responder às seguintes questões considerem o seguinte:

Atividades físicas vigorosas referem-se a atividades que requerem um esforço físico intenso que fazem ficar com a respiração ofegante.

Atividades físicas moderadas referem-se a atividades que requerem esforço físico moderado e tornam a respiração um pouco mais forte que o normal.

PAI

MÃE

Q.1 Diga-me por favor, nos últimos 7 dias, em quantos dias fez atividades físicas **vigorosas**, como por exemplo, levantar objetos pesados, cavar, correr, ginástica aeróbica, nadar, jogar futebol/basquete, andar de bicicleta a um ritmo rápido, fazer exercícios domésticos pesados (ex: esfregar o chão)?

_____ DIAS

_____ DIAS

Q.2 Nos dias em que pratica atividades físicas **vigorosas** pelo menos **10 minutos seguidos**, quanto tempo em média dedica normalmente a essas atividades (por dia)?

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Q.3 Diga-me por favor, nos últimos 7 dias, em quantos dias fez atividades físicas **moderadas** como por exemplo, carregar objetos leves, caçar, ginástica manutenção, trabalhos de doméstico (ex: varrer, aspirar, ...), trabalhos de carpintaria, andar de bicicleta a um ritmo normal ou ténis de pares? **Por favor NÃO inclua o "andar".**

_____ DIAS

_____ DIAS

Q.4 Nos dias em que faz atividades físicas **moderadas** pelo menos **10 minutos seguidos**, quanto tempo em média dedica normalmente a essas atividades (por dia)?

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Q.5 Diga-me por favor, nos últimos 7 dias, em quantos dias **andou** pelo menos **10 minutos seguidos** em casa ou no trabalho, por lazer, por prazer ou como exercício?

_____ DIAS

_____ DIAS

Q.6 Quanto tempo no total, despendeu num desses dias, a andar/caminhar?

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Q.7 Diga-me por favor, num dia normal da semana quanto tempo passa sentado? Isto pode incluir o tempo que passa a uma secretaria (estudar, computador), a visitar amigos, a ler, a estudar, a brincar com os filhos, a ver televisão.
(some todos os momentos)

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Appendix 2: Informed consent

**O Futebol como uma nova abordagem terapêutica no combate
ao excesso de peso e obesidade pediátrica**

CONSENTIMENTO INFORMADO

Eu, abaixo-assinado, _____,

na qualidade de representante legal do educando _____

_____, fui informado de que o estudo de investigação acima mencionado se destina a avaliar a influência da prática de futebol em indicadores cardiometabólicos, na aptidão física e no bem-estar psicológico de crianças. Tomei conhecimento que irá ser oferecida, de forma gratuita, a oportunidade de praticar exercício físico regular sob a orientação de profissionais. Sei que está prevista a realização de duas avaliações, no início e no final do estudo, relacionadas com a aptidão física e a saúde, que incluem:

- a) Colheita de sangue (9 mL) por punção venosa. A colheita de sangue permitirá realizar a avaliação de diversos marcadores de risco cardiometabólico pelo que os participantes beneficiarão de um estudo analítico mais alargado, através do seu médico responsável. Alguns dos estudos que vão ser efectuados são estudos genéticos, respeitando o estabelecido no Decreto-Lei 12/2005, de 26 de Janeiro. No caso de serem descobertos dados relevantes será facultada aos participantes a possibilidade de os conhecer e de ter o devido aconselhamento médico e acompanhamento psicológico. Sei que uma parte do sangue vai ser utilizada de imediato para fazer algumas análises e que outra parte vai ser armazenada (cerca de dois anos) para ser analisada posteriormente;
- b) Avaliação da composição corporal e da densidade mineral óssea através da medição do perímetro da cintura, e recorrendo a uma balança de bio-impedância e densitometria (DXA). O DXA apesar de emitir radiação (Raio-x), a sua dosagem é extremamente reduzida, equivalendo a um dia de exposição solar normal, não havendo qualquer contraindicação de aplicação em crianças a partir dos 3 anos de idade;
- c) Avaliação do estádio maturacional através da escala de Tanner;
- d) Medidas de pressão arterial, frequência cardíaca e variabilidade cardíaca em repouso;
- e) Avaliação do volume de oxigénio máximo ($VO_{2\text{máx}}$) avaliado através de um protocolo de exercício incremental num tapete rolante.

Foi-me garantido que todos os dados relativos à identificação dos participantes neste estudo são confidenciais e que a utilização das amostras será apenas no âmbito do estudo.

Sei que posso recusar-me a autorizar a participação ou interromper a qualquer momento a participação no estudo do menor de idade de que sou responsável, sem nenhum tipo de penalização por este facto. Compreendi a informação que me foi dada, tive oportunidade de fazer perguntas e as minhas dúvidas foram esclarecidas.

Autorizo de livre vontade a participação daquele que legalmente represento no estudo acima mencionado. Concordo que sejam efetuados os exames e a colheita de amostras de sangue para realizar as análises que fazem parte deste estudo. Também autorizo a divulgação dos resultados obtidos no meio científico, garantindo o anonimato.

Assinatura _____ Data [Ano/mês/dia] 20____/____/____.

**Appendix 3: Children's attraction to physical activity
questionnaire (CAPA)**

Atração para a Atividade Física

Item	Exactamente como eu	Como eu				Exactamente como eu	Como eu
1	<input type="checkbox"/>	<input type="checkbox"/>	Alguns alunos divertem-se mais a jogar ou a praticar desportos do que a fazer outras coisas	MAS	Outros alunos gostam mais de fazer outras coisas	<input type="checkbox"/>	<input type="checkbox"/>
2	<input type="checkbox"/>	<input type="checkbox"/>	Alguns alunos não gostam muito de praticar jogos e desportos	MAS	Outros alunos gostam muito de praticar jogos e desportos	<input type="checkbox"/>	<input type="checkbox"/>
3	<input type="checkbox"/>	<input type="checkbox"/>	Alguns alunos têm colegas que lhes dizem que eles não são muito bons a praticarem jogos e desportos	MAS	Outros alunos têm colegas que lhes dizem que eles são bons a praticarem jogos e desportos	<input type="checkbox"/>	<input type="checkbox"/>
4	<input type="checkbox"/>	<input type="checkbox"/>	Alguns alunos são gozados por outros quando praticam jogos e desportos	MAS	Outros alunos não são gozados por outros quando praticam jogos e desportos	<input type="checkbox"/>	<input type="checkbox"/>
5	<input type="checkbox"/>	<input type="checkbox"/>	Alguns alunos pensam que quantos mais jogos e desportos fizerem melhor	MAS	Outros alunos pensam que não é bom fazer demasiados jogos e desportos	<input type="checkbox"/>	<input type="checkbox"/>

Appendix 4: Quality of life questionnaire

Este 2 questionários enquadram-se no Projeto “**Futebol é Saúde**”, no qual o seu filho/a está a participar.

Estimamos que, na sua totalidade, demore cerca de **20** minutos a ser preenchido.

Obrigada pela atenção dispensada.

Quem preencheu o questionário:

Mãe Pai

Outro: _____

CARACTERÍSTICAS DO SEU/SUA FILHO/A:

Data de Nascimento | _____._____._____|
 dia mês ano

	A que horas se deita:	A que horas se levanta:
Em média, num <u>dia normal de semana</u>	____ Horas ____ Min	____ Horas ____ Min
Em média, num <u>dia de fim-de-semana</u>	____ Horas ____ Min	____ Horas ____ Min

Em média, quanto tempo é que o seu filho passa a ver TV, jogar videojogos e no computador? (some todos os momentos)

Num dia normal de semana	<input type="checkbox"/> <30min	<input type="checkbox"/> 30 min	<input type="checkbox"/> 1h	<input type="checkbox"/> 2h	<input type="checkbox"/> 3h	<input type="checkbox"/> >3h
Num dia de fim de semana	<input type="checkbox"/> <30min	<input type="checkbox"/> 30 min	<input type="checkbox"/> 1h	<input type="checkbox"/> 2h	<input type="checkbox"/> 3h	<input type="checkbox"/> >3h

De acordo com o Boletim de Saúde: (se preferir pode anexar uma fotocopia da página 2 e 3 do *Boletim de Saúde Infantil e Juvenil* do seu filho(a))

	<u>Peso</u>	<u>Comprimento/Altura</u>

Pratica Atividade Física organizada fora da escola? Sim Não

Se Sim, qual/quais:

<u>Tipo de Atividade</u>	<u>Nº de vezes por semana</u>							<u>Duração de cada sessão</u>				<u>Dia(s) da semana</u>
	1x	2x	3x	4x	5x	6x	7x	30'	45'	1h	1h30	
	1x	2x	3x	4x	5x	6x	7x	30'	45'	1h	1h30	
	1x	2x	3x	4x	5x	6x	7x	30'	45'	1h	1h30	

Exemplo:

Karaté 1x 2x 3x 4x 5x 6x 7x 30' 45' 1h 1h30 Segunda e Sexta

Qual o transporte que utiliza para ir para a escola?

carro autocarro mota a pé Outro: _____

quanto tempo demora no percurso casa-escola? _____ minutos

Qual o seu tipo de habitação:

apartamento moradia Outro: _____

No local onde vive, é possível que o seu filho brinque no exterior? SIM NÃO

Se Sim, onde? na rua num parque junto à sua casa no quintal/jardim de casa no parque infantil

Se não, qual o motivo? não tem quintal/jardim em casa a rua tem muito tráfego não há parque infantil

a rua é perigosa em termos criminais, Outro: _____

	NUNCA	RARAMENTE	OCASIONALMENTE	FREQUENTEMENTE	SEMPRE
o meu/minha filho/a é naturalmente muito ativo	<input type="checkbox"/>				
o meu/minha filho/a precisa de mim para ter motivação para brincar	<input type="checkbox"/>				
o meu/minha precisa de companhia (amigos, Irmãos, pais) para ter motivação para brincar	<input type="checkbox"/>				

Comparando com crianças da mesma idade, considera o seu/sua filho/a:

- MUITO MAIS ACTIVO
- MAIS ACTIVO
- IGUAL
- MENOS ACTIVO
- MUITO MENOS ACTIVO

O/A seu/sua filho/a com quem vive: PAI MÃE IRMÃOS AVÓ AVÔ OUTROS: _____

Quantas horas por dia, o/a seu/sua filho/a passa na escola? |_____|Horas |_____|Min

Quantos televisores têm em sua casa? 1 2 3 4 >4

O seu/sua filho/a tem televisão no quarto? SIM NÃO

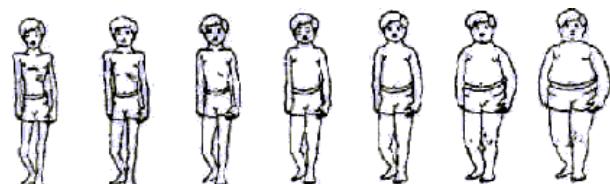

Tem computadores (fixos e portáteis) em sua casa? SIM NÃO **Se sim, quantos** _____

Tem videojogos (nitendo, playstation, wii, gameboy) em sua casa? SIM NÃO **Se sim, quantos** _____

Durante as refeições a televisão está ligada e a atenção está centrada na televisão? SIM NÃO

Acha que seu filho tem, neste momento, um Peso Muito Baixo Baixo Ligeiramente Magro Normal
 Ligeiramente com excesso de peso Excesso Peso Obesidade

Qual destas figuras é semelhante ao seu filho(a)?

1 2 3 4 5 6 7

1 2 3 4 5 6 7

(COLOQUE UM CÍRCULO NO NUMERO QUE SE ENCONTRA ABAIXO DA FIGURA ESCOLHIDA)

Organização do Sono (BISQ)

Por favor, coloque apenas uma resposta (a mais apropriada) em cada questão.

O seu filho/a dorme: em quarto próprio no quarto dos pais na cama dos pais
 em quarto partilhado com o irmão(s) OUTRO: _____

Em que posição o seu filho/a dorme a maior parte do tempo? de barriga para baixo de lado de costas

Quanto tempo o seu filho/a dorme durante a NOITE (entre as 19h da tarde e as 7h da manhã)?	_____ ____ Horas _____ ____ Min
Quanto tempo o seu filho/a dorme durante o DIA (entre as 7h da manhã e as 19h da tarde)?	_____ ____ Horas _____ ____ Min
Quanto tempo durante a noite o seu filho/a está acordado (entre as 22h da noite e as 6h da manhã)?	_____ ____ Horas _____ ____ Min
Quanto tempo é que o seu filho/a demora a adormecer?	_____ ____ Horas _____ ____ Min
A que horas o seu filho vai dormir?	_____ ____ Horas _____ ____ Min

Número de vezes o seu filho/a acorda por noite: ? nunca acorda 1 vez 2 vezes ≥3 vezes

Como é q o seu filho/a adormece? enquanto toma o biberão embrulhado com ajuda
 na cama sozinho na cama junto aos pais OUTRO: _____

Acha q o seu filho/a tem problemas de sono? problemas muito sérios
 pequenos problemas
 Não tem problemas

Escala de Regulação Emocional (ERRS)

Por favor, classifique o seu filho de acordo com as descrições abaixo, colocando um círculo no número mais adequado. O número 4 que está sublinhado no centro representa o ponto médio no qual a criança se poderá situar nesse item. Por favor esteja à vontade para usar todas as possíveis opções de resposta..

	Não é provável							Muito provável
	1	2	3	4	5	6	7	
1. Depois de receber de alguém um presente que não gosta, qual a probabilidade do seu filho fingir que gosta do presente?	1	2	3	<u>4</u>	5	6	7	
2. Depois de ver alguém tropeçar ou cair de uma forma engraçada, qual a probabilidade do seu filho rir à gargalhada?	1	2	3	<u>4</u>	5	6	7	
3. Depois do seu filho comer algo que lhe sabe mal, qual a probabilidade dele cuspir a comida ou reagir negativamente?	1	2	3	<u>4</u>	5	6	7	
4. Num contexto mais sério, como uma igreja ou um funeral, qual a probabilidade do seu filho entender e se comportar adequadamente à situação?	1	2	3	<u>4</u>	5	6	7	
5. Se lhe for pedido para guardar um segredo (p. ex., não falar ao irmão sobre a festa de aniversário surpresa), qual a probabilidade do seu filho manter o segredo?	1	2	3	<u>4</u>	5	6	7	
6. Qual a probabilidade do seu filho ajudar os outros (p. ex., amigo / irmão) a manter um segredo de forma a evitar um castigo? (p. ex., não contar à mãe que um irmão partiu um vaso)	1	2	3	<u>4</u>	5	6	7

QUESTÕES RELACIONADAS COM A GRAVIDEZ:

Idade que tinha quando engravidou do/da seu/sua filho/a? _____

Quantos filhos tem? _____ Que idade têm? _____

Recorde-se da alimentação do bebé no 1ºano de vida, durante quanto tempo foi amamentado, **só com leite materno?**

Não foi amamentado _____

Foi amamentado: quanto tempo: _____ dias ou _____ semanas ou _____ meses

Em que altura (dias, meses ou semanas), lhe introduziu **outro alimento**, além leite materno?

_____ dias ou _____ semanas ou _____ meses

Que alimento foi? (assinalar com uma cruz)

Leite de vaca Leite de lata Papas Sopa Outro: Qual? _____

Qual o seu peso no início da Gravidez do seu filho? _____ Kg e no final? _____ Kg

Quantos quilos no total, aumentou no seu peso, durante a gravidez? _____ Kg

Teve diabetes gestacional? Sim Não

Teve pré-eclampsia? Sim Não
(tensão arterial elevada)

Teve de alteração a sua alimentação durante a gravidez? Sim Não Se sim, motivo? _____

O/A seu/sua filho/a nasceu com quantos meses ou semanas de gestação: _____ semanas (**Ex: 38 semanas**)

Tipo de Parto? Parto Normal Cesariana

Fumou durante a Gravidez? Sim Não Se Sim, quantos por dia? _____

Manteve ou reduziu o consumo de tabaco? _____

ACTIVIDADE FÍSICA HABITUAL DOS PAIS

Questionário Internacional de Atividade Física (IPAQ)

As questões que lhes vou colocar, referem-se à semana imediatamente anterior, considerando o tempo em que esteve fisicamente ativo/a. Por favor, respondam a todas as questões, mesmo que não se considerem pessoas fisicamente ativas. Vou colocar-lhes questões sobre as atividades desenvolvidas na vossa atividade profissional e nas vossas deslocações, sobre as atividades referentes aos trabalhos domésticos e às atividades que efetuam no vosso tempo livre para recreação ou prática de exercício físico / desporto.

Ao responder às seguintes questões considerem o seguinte:

Atividades físicas vigorosas referem-se a atividades que requerem um esforço físico intenso que fazem ficar com a respiração ofegante.

Atividades físicas moderadas referem-se a atividades que requerem esforço físico moderado e tornam a respiração um pouco mais forte que o normal.

PAI

MÃE

Q.1 Diga-me por favor, nos últimos 7 dias, em quantos dias fez atividades físicas **vigorosas**, como por exemplo, levantar objetos pesados, cavar, correr, ginástica aeróbica, nadar, jogar futebol/basquete, andar de bicicleta a um ritmo rápido, fazer exercícios domésticos pesados (ex: esfregar o chão)?

_____ DIAS

_____ DIAS

Q.2 Nos dias em que pratica atividades físicas **vigorosas** pelo menos **10 minutos seguidos**, quanto tempo em média dedica normalmente a essas atividades (por dia)?

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Q.3 Diga-me por favor, nos últimos 7 dias, em quantos dias fez atividades físicas **moderadas** como por exemplo, carregar objetos leves, caçar, ginástica manutenção, trabalhos de doméstico (ex: varrer, aspirar, ...), trabalhos de carpintaria, andar de bicicleta a um ritmo normal ou ténis de pares? **Por favor NÃO inclua o "andar".**

_____ DIAS

_____ DIAS

Q.4 Nos dias em que faz atividades físicas **moderadas** pelo menos **10 minutos seguidos**, quanto tempo em média dedica normalmente a essas atividades (por dia)?

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Q.5 Diga-me por favor, nos últimos 7 dias, em quantos dias **andou** pelo menos **10 minutos seguidos** em casa ou no trabalho, por lazer, por prazer ou como exercício?

_____ DIAS

_____ DIAS

Q.6 Quanto tempo no total, despendeu num desses dias, a andar/caminhar?

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.

Q.7 Diga-me por favor, num dia normal da semana quanto tempo passa sentado? Isto pode incluir o tempo que passa a uma secretaria (estudar, computador), a visitar amigos, a ler, a estudar, a brincar com os filhos, a ver televisão.
(some todos os momentos)

_____ HORAS _____ MIN.

_____ HORAS _____ MIN.
